ABSTRACT

Introduction
Epilepsy is one of the most common chronic neurological disorders requiring prolonged treatments and drugs. According to The World Health Organization (WHO), epilepsy is one of those serious brain disorders that affect not only the individual but has a deep impact on the family and society in general. Approximately 50 million people are affected with epilepsy around the world36, though proper epidemiological studies do not exist for Pakistan it is estimated that the prevalence of epilepsy is 9.99/1000. Highest prevalence is seen in people younger than 30 years of age, i.e. about 2 million people and 1/10th of the world burden of epilepsy is in Pakistan! The guidelines available in developed countries are gauged in a setting where epilepsy care is provided by epileptologists/neurologists. In Pakistan the scenario is different, there is only one neurologist for 1.4 million (14lac) population contrast to US where one neurologist for 26 thousand people 29. So there is a desperate need to adapt to alternate guidelines with strategies to provide epilepsy management at a primary care level and to standardize epilepsy care on a National level.

Methods
To form these guidelines we reviewed and adopted from many different available guidelines mainly
1. Local adaptations of the WHO recommendations4
2. Modification of the ILAE treatment guide lines: evidence based analysis of AEDs 200611
3. Updated ILAE evidence review of AEDs special report 201312
4. Existing guidelines in other low income countries13-15
5. NICE, AAN, AES recommendations.17-21

Results
These guidelines consist of
1. The universally ILAE accepted definition and classification of epilepsy and Epileptic syndromes with A step wise approach to a patient with seizures and epilepsy in Pakistan.
2. Tables Selecting the right drug with evidence based references keeping in mind the cost and availability in Pakistan.
3. AED selection in special populations e.g. women20, children17 and elderly
CONCLUSION

The primary scope of these guidelines is to provide a concise practical management plan which considers the role of AEDs especially their judicial use. These guidelines hope to provide the physicians treating epilepsy patients with a step wise cost effective approach to the patient with epilepsy. A separate guideline to classification and diagnosis is also available, and the guidelines in entirety are also available online at the Pakistan Society of Neurology website.

Guidelines Introduction

Epilepsy is one of the most common chronic neurological disorders requiring prolonged treatments and drugs. It is a disorder that is widely misunderstood and carries a vicious stigma. Epilepsy comprises a vast group of disorders and syndromes with one common symptom, “The Seizure”. For the purpose of these guidelines we have integrated the International League Against Epilepsy (ILAE) definitions of seizures and epilepsy. There is a vast array of literature and guidelines that exist in developed countries for over a decade. These have been reviewed and compiled and modified to suit the Pakistani population and socioeconomic status. These guidelines hope to help improve medical decision making in Pakistan while treating the patient with epilepsy (PWE).

THE NEED FOR NATIONAL GUIDELINES FOR EPILEPSY IN PAKISTAN:

Epilepsy has varied etiologies and affects all age groups, but the vast majority of cases are treatable with Anti Epileptic Drugs (AEDs) most of which are easily available. However knowledge about epilepsy and its care is extremely low. The majority of people with epilepsy (PWE) are treated inadequately or inappropriately. According to The World Health Organization (WHO), epilepsy is one of those serious brain disorders that affect not only the individual but has a deep impact on the family and society in general. Approximately 50 million people are affected with epilepsy around the world, and this number will increase with the new definition. Though proper epidemiological studies do not exist for Pakistan it is estimated that the prevalence of epilepsy is 9.99/1000. Highest prevalence is seen in people younger than 30 years of age. That is: about 2 million people and 1/10th of the world burden of epilepsy is in Pakistan. The recent estimates of population of Pakistan exceed 180 million, whereas the total number of trained neurologists in Pakistan is estimated to be 135 (Pakistan Society of Neurology Directory 2013). Based on the available data, the estimated 2 million people suffering from epilepsy in Pakistan, makes it one neurologist available for every 15200 sufferers of epilepsy with only few trained in epilepsy. Despite efforts to create awareness there remains a wide treatment gap and misconception. The guidelines available in developed countries are gauged in a setting where epilepsy care is provided by epileptologists/neurologists. In Pakistan it is a different scenario, there is only one neurologist for 1.4 million population contrast to US where one neurologist for 26 thousand people. So there is a desperate need to adapt to alternate guidelines with strategies to provide epilepsy management at a primary care level and to standardize epilepsy care on a National level. The primary care physicians in civil hospitals and dispensaries, and general practitioners (GPs), form the crux of health care in Pakistan and therefore see most of the PWE. Unfortunately neurology rotation is not a mandatory in undergraduate training thus most lack the information and skill needed for proper epilepsy diagnosis and management. In 2011, WHO mental health Gap Action Programme (mhGAP) released evidence based epilepsy care guidelines for use in low and middle income countries. These guidelines provide a crudePerforma that requires local adaptation for use within individual countries. The guidelines state “For effective implementation and sustainability, the sense of ownership and empowerment must be transferred from the global health authorities to the local people. Socio-cultural and financial barriers that impede the implementation of the guidelines should be identified and ameliorated.”

**Variables Affecting Selection of AEDs in Pakistan**

Epidemiological studies of prevalence and incidence reviewed are problematic in Pakistan due to lack of proper data collection teams and resources. Data concerning seizure type, etiology, and severity of seizures are contrasted with those from developed countries. Sociocultural aspects of epilepsy have been poorly studied, and yet are fundamental to effective medical management. Thus the principles and success of treatment in Pakistan may differ considerably from developed countries. The principles of drug therapy may not be understood by patients, and the supply of drugs is often erratic; and these are major reasons for poor compliance with treatment. Therapy need to be prioritized to cost effectiveness, requiring a cheaper drug eg, phenobarbital to be tried as first line contrary to international guidelines. Computation of treatment gap figures in three developing countries suggest that between 80-94% of patients with active epilepsy are not receiving anticonvulsant therapy, cost and cultural belief are two of the main factors.

To form these guidelines we reviewed and adopted from many different available guidelines mainly.

1) Local adaptations of the WHO recommendations (4)
2) Modification of the ILAE treatment guidelines: based analysis of AEDs 2006 (11)
3) Updated ILAE evidence review of AEDs special report 2013 (12)
4) Existing guidelines in other low income countries (13,14,15,16)
5) NICE guidelines (17)
6) AAN practice parameters, (18)
7) AES recommendations. (19)
8) A multitude of literature to support our selection and recommendations (20-43)

**Management Guidelines:**

**QUESTIONS ADDRESSED**

**Q1-Q3:** AEDs Initiation of therapy/Mono therapy; Adjuvant therapy; Cessation of therapy

**Q4-Q7:** Women (fertility, contraception, conception, pregnancy, lactation, teratogenicity), Children, elderly differences

**Q8-Q9:** Status Epilepticus in Adults and children (protocols)

**Q10-Q13:** Access to medications, direct and indirect costs, co-morbid conditions, preventable causes

**Q14-Q15:** Alternate Therapies, diet.

**Q16:** Epilepsy surgery.

**Q17-Q19:** Lifestyle, Career choices, Driving.

**Q20-23:** Epilepsy Diaries, lockets, keychain or bracelets, Help line.

**Monotherapy Guideline questions:**

**Q1-Q3:** Patients (adults/elderly/children) with partial-onset seizures

**Q4-Q5:** Patients (adults/children) with generalized-onset tonic-clonic seizures

**Q6:** Children with idiopathic localization-related epilepsies and syndromes (BEATS).

**Q7-Q8:** Children with idiopathic-generalized epilepsies (CAE, JME).

**Q9:** Special Issues related to Women.

**Q10:** Considerations in Elderly and Multiple handicapped

Questions 6-10 are discussed in the special population subset of these guidelines not published in this edition.

**A person is considered to have epilepsy if they meet any of the following conditions:**

At least two unprovoked (or reflex) seizures occurring greater than 24 hours apart.
One unprovoked (or reflex) seizure and a probability of further seizures similar to the general recurrence risk (at least 60%) after two unprovoked seizures, occurring over the next 10 years.
Diagnosis of an epilepsy syndrome
For Classification and Diagnosis guidelines see Appendix A

MANAGEMENT OF EPILEPSY

Non-pharmacological Management:

Once diagnosis is made patient and family members need to be counselled empathically. Since the disease still carries a strong stigma, confidentiality needs to be maintained at all steps, and the condition should be discussed with any family member with consent of the PWE.

- Establish the diagnosis
- Education/ counselling
- Address psychosocial issues
- Lifestyle modifications

Patients need counselling regarding the

- Disease
- Prognosis
- Need for medication
- Compliance
- Life style

Life style modification includes

- Adequate sleep - early to bed early to rise
- Change in job e.g. occupation, driving, swimmers, boxers, airplane pilots etc.
- Avoidance of alcohol, stimulants, energy drinks, gutka, JM, etc.
- Stress reduction — specific techniques, Yoga, meditation, early morning walks
- Adequate diet – high protein. Low carbohydrate, Vit. D, B rich diet
- Joining support groups
- Avoid social isolation

Pharmacological treatment of epilepsy

The mainstay of treatment for epilepsy is antiepileptic drugs (AEDs) taken daily to prevent the recurrence of epileptic seizures. It is important that the treatment strategy and suitability of the AED is determined by the prescriber keeping the individual with epilepsy and the carer informed before drug therapy is started.

When to Start AEDs after first seizures

Whether to treat first seizure is controversial studies show 16-62% recur within 5 years, Relapse rate is reduced by antiepileptic drug treatment, and it is now recommended that since Neurological abnormalities, abnormal imaging, abnormal EEG or family history increase relapse risk these patients should be treated after first seizure.

The diagnosis of epilepsy needs to be critically evaluated if events continue despite an optimal dose of a first line AED. Before combination therapy is considered, PWE should be given a trial of at least 2-3 appropriate monotherapy regimens, with caution during the transition.

General Recommendations:

1) It is recommended that PWE should be treated with a single AED (monotherapy). If the initial treatment is unsuccessful, then monotherapy using another drug can be tried.
2) Caution is needed during the changeover period, with the second drug titrated and the first drug decreased gradually.

3) It is recommended that combination therapy (adjunctive or ‘add-on’ therapy) should only be considered when attempts at monotherapy with AEDs have not resulted in seizure control.

4) If trials of combination therapy do not bring about worth while benefits, Diagnosis should be revisited and treatment should revert to the regimen with best control providing efficacy in reducing seizures and tolerability of side effects.

5) Refer to specialist for phase II evaluation and Epilepsy surgery, classify and diagnose cause of refractory epilepsy, epileptic or non-epileptic fits.

6) If an AED has failed because of adverse effects or continued seizures, a second drug should be started (which may be an alternative first-line or second-line drug) and built up to an adequate or maximum tolerated dose and then the first drug should be tapered off slowly.

7) If the second drug is unhelpful, either the first or second drug may be tapered, depending on relative efficacy, side effects and how well the drugs are tolerated before starting another drug.

8) It should be recognised that some PWEs (through their families in some instances) may choose not to take AED therapy following a full discussion of risks and benefits. Reason should be sought and addressed accordingly. Treatment should be insisted upon if risk of recurrence is high as described in table 3.

9) Treatment of a first unprovoked seizure reduces the risk of recurrence in the short-term. In children, treatment of a first unprovoked seizure does not alter the long-term prognosis for seizure remission.

10) AED therapy should only be started once the diagnosis of epilepsy is confirmed, except in exceptional circumstances that require discussion and agreement between the physician and the PWE and/or carers as appropriate.

11) Continuing AED therapy should be planned by the physician. It should be part of the PWE agreed treatment plan, which should include details of how specific drug choices were made, drug dosage, possible side effects, and action to take if seizures persist.

12) When possible, choose which AED to offer on the basis of the presenting epilepsy syndrome. If the epilepsy syndrome is not clear at presentation, base the decision on the presenting seizure type(s).

13) Consistent supply to the PWE of a particular manufacturer’s AED preparation is recommended. Different preparations of some AEDs may vary in bioavailability or pharmacokinetic profiles and care needs to be taken to avoid reduced effect or excessive side effects.

14) Where partial seizures are suspected prefer sodium channel blockers as first line AEDs (see fig 1).

15) Where generalized seizure syndromes are suspected consider broader spectrum AEDs (see fig 1).

16) Phenobarbitone is a broad spectrum efficacious AED that is easily available in Pakistan at minimal price, therefore should still be considered as first line therapy where affordability is an issue as risk of seizures outweigh the long term side effects.

17) Phenobarbitone should be offered where compliance due to cost is suspected.

18) If using carbamazepine, check LFTs.

19) When prescribing sodium valproate to women and girls of present and future childbearing potential, discuss the possible risk of malformation and neurodevelopmental impairments in an unborn child, particularly with high doses of this AED or when using as part of polytherapy. Vit B, folate and calcium supplements should be added.

20) Lamotrigine should be administered with caution and slow titration when given as monotherapy and with even slower titration when combined with inducers like valproate to avoid the risk of idiosyncratic reactions like Steven Johnson’s syndrome and toxic epidermolysis. All patients should be counseled and warned to stop medication and contact the physician immediately if any rash appears.

21) Levitiracetam should be given with neuropsychiatric issues in mind and pyridoxine supplement.

22) Maintain a high level of vigilance for treatment emergent adverse effects (for example, bone health issues, blood dyscrasias, and neuropsychiatric issues)
23) If management is complicated, PWE should be referred to a specialist.
24) The prescriber must ensure that the PWE and/or carers as appropriate are fully informed about treatment including action to be taken after a missed dose or after a gastrointestinal upset.
25) Regular blood test monitoring in PWE is not recommended as routine, and should be done only if clinically indicated or non-compliance is suspected as below.

Examples of blood tests include:
Before surgery – clotting studies in those on sodium valproate. For Patients on enzyme inducing AEDs: CBC, Electrolytes, LFTs, Vit D levels, every 1-2 years. Test for serum amino acids, TSH and urine for organic acids in all children with neonatal non-infectious seizures and refractory seizures.

26) Asymptomatic minor abnormalities in test results are not necessarily an indication for changes in medication.
27) Every patient when stable should still have a 6 monthly follow-up to ensure compliance, and review treatment plan and side effects.
28) For uncontrolled patients treatment should be reviewed at regular intervals so PWE are not maintained for long periods on treatment that is ineffective or poorly tolerated, when in doubt early referral is more cost effective.

29) **Compliance can be optimized with the following:**
   - Educating PWE and their families and/or carers in the understanding of their condition and the rationale of treatment. 
   - Reducing the stigma associated with the condition. 
   - Using simple medication regimens. 
   - Positive relationships between healthcare professionals PWE, and their family. 
   - SMS bulk reminder module.

30) The risks and benefits of continuing or withdrawing AED therapy should be discussed with PWE and/or carers as appropriate, who have been seizure free for at least 2 years At the end of the discussion, they should understand their risk of seizure recurrence off treatment. This discussion should take into account details of the PWE’s epilepsy syndrome, prognosis and life style.

31) When AED treatment is being discontinued in PWE who has been seizure free, it should be carried out slowly (at least 2-3 months) and one drug should be withdrawn at a time.

32) Particular care should be taken when withdrawing benzodiazepines and barbiturates (may take up to 6 months or longer) because of the possibility of drug-related withdrawal symptoms and/or seizure recurrence.

33) PWE and carer should be counseled whereby if seizures recur the last dose reduction is reversed and medical advice is sought.

---

**INTRODUCTION**

Hepatic encephalopathy is a common neuro-psychiatric condition that occurs in patients with liver disease, particularly cirrhosis or end-stage liver disease. It is characterized by altered mental status, including confusion, disorientation, and coma, and is associated with elevated ammonia levels in the blood and brain. The pathophysiology of hepatic encephalopathy involves the accumulation of ammonia in the brain, which disrupts neurological function. Various medications and therapies are used to manage hepatic encephalopathy, including ornithine-aspartate (LOLA) therapy, which has been shown to improve clinical symptoms and reduce serum ammonia levels in some studies. However, the efficacy of LOLA therapy remains controversial, with some studies reporting significant clinical improvement and reduced ammonia levels, while others do not find it statistically significant.

**MATERIAL & METHOD**

The study was a randomized, placebo-controlled trial designed and reported according to CONSORT guidelines. Patients with hepatic encephalopathy were recruited from the gastroenterology department at a tertiary care hospital in Pakistan. The inclusion criteria for the study were adult patients with a diagnosis of hepatic encephalopathy, as defined by the West Haven criteria, and a serum ammonia level of 50 micromol/L or higher. The exclusion criteria included patients with severe renal or hepatic failure, recent use of ornithine-aspartate therapy, and active sepsis.

The study included two groups: a trial group receiving ornithine-aspartate infusions and a placebo group receiving saline infusions. The primary outcome measure was the change in serum ammonia levels, and secondary outcomes included clinical improvement as assessed by the West Haven criteria and sonographic findings of hepatic encephalopathy.

**RESULTS**

In the trial group, the mean serum ammonia level was 105.2 micromol/L, while in the placebo group, it was 118.5 micromol/L. The difference was statistically significant (p-value 0.0013). Furthermore, 12 patients in the trial group showed a decrease in serum ammonia levels, compared to 5 patients in the placebo group, with a p-value of 0.124. The most common adverse effects reported in the trial group were nausea and vomiting, occurring in 24% of patients, and diarrhea, occurring in 36% of patients.

**CONCLUSION**

Ornithine-aspartate therapy showed promise in improving serum ammonia levels and reducing clinical symptoms of hepatic encephalopathy, especially when not responsive to other interventions. However, further studies are needed to confirm these findings and to investigate the long-term effects of ornithine-aspartate therapy in the management of hepatic encephalopathy.
Not available in Pakistan or difficult to get
**Felbamate - Patients are usually electively admitted when initiating this AED due to the incidence of fatal liver failure and aplastic anaemia, for routine lab observation.
***Vigabatrin - Its use is restricted to whom all other combinations are inadequate or not tolerated. It must only be initiated by a Neurologist. All patients must have visual field testing prior to commencement and every 6/12 thereafter.
# Rash All AEDs carry the risk of rash, however the drugs highlighted as Rash carry a risk of Stevens - Johnsons Syndrome.
• Enzyme inducers and affect the metabolism of other drugs, for example Oral Contraceptives; women need to be alerted of this interaction.
weak enzyme inducers and may affect the metabolism of other drugs at high doses.
• Signs and Symptoms of Toxicity: vary from drug to drug however the following may indicate possible toxicity: Diplopia, blurred vision, unsteady gait, excessive tiredness, new onset of dizziness.
• GIT Dist may manifest as anorexia, nausea, vomiting dyspepsia, constipation, diarrhoea or any s/s of GI disturbance Interactions between antiepileptic drugs are complex and may enhance toxicity without a corresponding increase in antiepileptic effect. Interactions are usually caused by hepatic enzyme induction or hepatic enzyme inhibition. These interactions are highly variable and unpredictable.

### AED INTERACTIONS

Some common interactons between antiepileptic drugs and non-antiepileptic drugs are listed below in table 7. For a full list consult the PDR Summary of Product Characteristics for each drug.

**Note**
- Enzyme inducing AED’s increase the rate of metabolism of Warfarin and The INR should be monitored carefully when an enzyme AED is added or discontinued.
- Aspirin enhances valproate and phenytoin effects.
- Antibiotics, macrolides (clarithromycin/erythromycin) increase the plasma concentration of carbamazepine and inhibit the metabolism of phenytoin. Erythromycin possibly inhibits the metabolism of valproate.
- Meropenem, reduces plasma concentrations of valproate.
- Rifamycins accelerate phenytoin metabolism.
- Analgesics, NSAIDs enhance the effects of phenytoin.
- Estrogens, enzyme inducing drugs accelerate metabolism of Estrogens reducing contraceptive effects. Estrogens reduce lamotrigine levels.
- Plasma concentration of lamotrigine increased by valproate.
LOLA was beneficial in both overt and minimal hepatic studies. Bai et al concluded after meta-analysis of 8 effects not only in clinical improvement of encephalopathy but also in detoxification of ammonia. L Ornithine L aspartate (LOLA) therapy is safe, with mild side effects like infections have become endemic in our community.18,19 In our study, it was observed that the LOLA has beneficial effects on ammonia. High levels of ammonia in the body were recorded as frequency and percentage. Patients on standard treatment regimen. CONCLUSION the over encephalopathy. In the review of local data, we can recommend use of LOLA as addition to existing data and paucity of local data, we conducted a study to observe effect of LOLA on clinical improvement of encephalopathy. 3,4 In hepatic encephalopathy, Acetaminophen and Alcohol are well known causes. Clinical grading of hepatic encephalopathy was recorded as mean and standard deviation, nominal data were compared by paired t-test. A p-value of < 0.05 was considered statistically significant.

Initiation of AEDs Drug choice with seizure type:

Treatment (Monotherapy) of patients with newly diagnosed focal (partial, complex partial and secondarily generalized) seizures:

A) Adults with focal(partial) onset seizures (ILAE 2013)

RECOMMENDATIONS

1) Offer CBZ/ OXC or PB (where cost is an issue) as first line treatment as first line treatment to patients with newlydiagnosed focal seizures.
2) Offer LTG, PHT, OXC or VPA if CBZ and PB are unsuitable or not tolerated. If the first AED tried is ineffective, offer an alternative from these 5 AEDs. (Be aware of the teratogenic risks of sodium valproate and idiosyncratic rash of lamotrigine )
3) Consider adjunctive treatment if a second well tolerated AED is ineffective
4) If adjunctive treatment is ineffective or not tolerated, discuss with, or refer to, an epilepsy specialist or neurologist. Other AEDs that may be considered by the epilepsy specialist are eslicarbazepine acetate (ECA), clobazam, lacosamide, phenytoin, pregabalin, tiagabine, vigabatrin and zonisamide. Carefully consider the risk benefit ratio when using vigabatrin because of the risk of an irreversible effect on visual fields.

Pharmacological management (monotherapy) of Adults with newly diagnosed Generalized Epilepsy Syndromes (IGE).

The absence of class I and II RCTs (randomized controlled trials) for adults with GTC seizures implies a marked deficiency in published studies. No AED has reached the highest level of evidence (level A and B) for efficacy. VPA, LTG, TPM, OXC, PB, PHT, TPM, and CBZ are possibly level C, and GBP, LEV, and VGB are
potentially level D efficacious/effective as initial monotherapy for adults with newly diagnosed or untreated generalized onset tonic-clonic seizures. Class IV evidence suggests that CBZ and PHT and other sodium channel blockers may precipitate or aggravate generalized onset seizures. (ILAE updates 2013).

RECOMMENDATIONS

1) Offer sodium valproate as first-line treatment to adults with newly diagnosed GTCs. (Be aware of teratogenic risks of sodium valproate in women of child bearing age)

2) Offer lamotrigine if sodium valproate is unsuitable. If the person has myoclonic seizures or is suspected of having juvenile myoclonic epilepsy (JME), (be aware that lamotrigine may exacerbate myoclonic seizures. Be aware of idiosyncratic reaction of lamotrigine by slow escalation)

3) Consider leviracetam and Phenobarbital in patients where VPA and LTG are not suitable.

4) Offer clobazam, CBZ, OXC and TPM as adjunctive treatment to adults with GTC seizures if first line treatments as above are ineffective or not tolerated. (Be aware of the risk of exacerbating myoclonic or absence seizures with CBZ and OXC)

5) If there are absence or myoclonic seizures, or if JME is suspected, do not offer carbamazepine, gabapentin, oxcarbazepine, phenytoin, pregabalin, tiagabine or vigabatrin.

KETOCGENIC DIET

INTRODUCTION

The ketogenic diet (KD) is a high fat, low carbohydrate and protein diet designed to mimic the biochemical response of the body to starvation when ketone bodies become the main fuel for the brain’s energy demands (Hartman 2008). It has long been used in the treatment of refractory epilepsy in children, although the exact mechanism of action is unclear. The KD diet was initially reported for use in epilepsy in 1921 (Wilder 1921). The initial diet used was the classical ketogenic diet, based on the ratio of fat to carbo-hydrate (with protein), of 3 or 4:1. Later an alternative was suggested using triglyceride oil as a supplement, the Medium chain Triglyceride (MCT) Diet (Huttenlocher et al 1971). These diets have to be carefully administered with the aid of a dietician.

- There is no evidence of efficacy of ketogenic diet in adults.
- 50% efficacy range is achieved in children.
- Recommended in refractory epilepsies in children where multiple regimens of AEDs proven ineffective.
- Local ketogenic reciepies are available and cost effective.

Epilepsy Surgery

**FDA approved surgical procedures:**

- Vagus nerve stimulation
- Surgical treatment

**Investigational:**

- Deep brain stimulation
- Gene therapy
• Laser Ablation

**Surgical Treatment**

- Upto 85% seizure-free rates
- **Resections:**
  - lesionectomy, lobectomy, hemispherectomy
- **Disconnections:**
  - Callosotomy, subpial transection, stereotactic ablations
- **Augmentations:**
  - Vagal, cerebellar, thalamic, deep brain stimulation

All patients with focal onset seizures that are refractory to an adequate trial of two or more AEDs of choice and are refractory to treatment should be referred for phase 1 surgical evaluation to an epilepsy specialist. All lesion-related Epilepsy syndromes should be considered for surgical management.

**SUMMARY:**

These guidelines hope to highlight the problems that exist in the care and management of epilepsy patients like Patient and physician awareness, social and cultural beliefs, easy access to treatment, misdiagnosis, inappropriate or inadequate treatment, sudden unexpected death that might have been prevented, preventable etiologies, Women with epilepsy, epilepsy in children, epilepsy in the elderly, advice about pregnancy and contraception and management of status epilepticus in children and adults. These guidelines will be revisited and modified on applicability every four years and it is vital that a spotlight is kept on the need to further develop variable services for people with epilepsy. The place of newly licensed drugs, stigmas, and cost for epilepsy also needs careful consideration. The primary scope of these guidelines is to provide a concise practical management plan which considers the role of AEDs especially their judicial use. The role of established and newly licensed drugs is considered with comparison of cost effectiveness. People with epilepsy remain at the centre of this guideline, and the need for services to consider the needs of each individual and their care givers have been focused. Attention has been paid to ensure that the recommendations are written in clear language and be accessible, and, I hope, useful to all. We remain committed to the care of people with epilepsy and commend these guidelines to you in that light.
