ABSTRACT

Background: Stroke is a common neurological disorder, leading cause of death and disability worldwide. Intra cerebral hemorrhage comprises of 10-15% of all strokes but associated with high risk of morbidity and mortality than cerebral infraction. The ICH Score is a good prognostic tool calculated very easily, when it is used to predict 30 day morality.

Objective: To determine the validity of Intracerebral hemorrhage score in predicting prognosis (adverse outcome or death) in patients of hemorrhagic stroke.

Material&Methods: This case series study was carried out at department of medicine Liaquat medical University Hospital Jamshoro and Hyderabad from June 16th 2012 to December 15th 2012. Eighty nine patients were enrolled in the study, non-probability consecutive sampling technique was applied and data was collected after inclusion and exclusion criteria and structured proforma were designed for study.

Results: Out of 89 patients 56 (62.9%) were male and mean age of the patients in our study was 65.14 years. In 32 (36%) patients ICH score was ≥ 3 while 57 (64%) patients had ICH score was < 3. Out of total 32 patients who had ICH score ≥ 3, Adverse outcome i.e. death occurred in 25 (78.12%) patients and males were 16 (80%) and 9 (75%) were female patients.

Conclusion: Frequency of adverse outcome (death) was found in 28.1% while ICH score predicted adverse outcome (death) in 36.1%. ICH score correctly predicted 77.77% adverse outcome, therefore we can conclude that ICH score is useful scale to predict mortality in patients suffering from intracerebral hemorrhage.

Key words: Intracerebral Hemorrhage, Intra cerebral hemorrhage score, Glasgow Coma Scale, Mortality

Introduction:

Stroke is defined as the sudden onset of focal neurological deficit due to a vascular cause. Stroke results from lack of blood flow to an area of the brain. Stroke is classified into ischemic and hemorrhagic stroke. Hemorrhagic stroke may be either cerebral haemorrhage or intra cranial haemorrhage and cerebral haemorrhage is either intra parenchymal haemorrhage or intra ventricular haemorrhage. Intracranial haemorrhage classified in to extra Duran hematoma, subdural hematoma and subarachnoid haemorrhage. Stroke is the common neurological disorder, leading cause of death in developing as well as in developed countries, prevalence in us is about 7 million (3.0%) and incidence varies according to age, sex, ethnicity and socioeconomic status [1].Worldwide 15 million people suffer from stroke each year, one third die and one-third are left permanently disabled[1][2].Stroke sub types vary in different parts of the world between different races but increased proportion of intracerebral haemorrhage and lacunar infarcts have been reported in Asia [3][4].Intra cerebral haemorrhage comprises of10-15% of all strokes but has a much higher risk of morbidity and mortality than cerebral infraction or subarachnoid haemorrhge (SAH) [5].Despite advances in the treatment of cerebral infraction and SAH, all hernatomas are not surgically accessible or their drainage doesn’t always improve outcome [6] and no known medical management strategy (like tissue plasminogen activator in ischemic stroke) in case of Intracerebral haemorrhge which improves the outcome of ICH so there should be some adequate scoring system which will help to predict prognosis of ICH [7].Standardization is a major issue for triage and subsequent management of such patients [8-9].Studies on ICH treatment has used a variety of selection criteria for patient’s inclusion but inconsistency of selection criteria across studies emphasize that there is no standard or widely accepted early prognostic model or clinical grading scale for ICH that analogous to those used for cerebral infraction, SAH, or traumatic brain injury.[10] [11] [12]. The excepted frequency of mortality in intracerebral haemorrhage is around 45% [13]. The prognosis of hemorrhagic stroke varies depending on the site and size of the haemorrhage. Lower Glasgow Coma Scale scores are associated with poorer
prognosis and higher mortality rate. A larger volume of blood at presentation is associated with a poorer prognosis. Growth of the hematoma volume is associated with a poorer functional outcome and increased mortality rate. Non aneuysmal peri mesencephalic has a less severe clinical course and in general better prognosis. The ICH Score utilizes combination of clinical information and CT scan recording [5], can be calculated very easily and this may be a good prognostic tool when used to predict 30 day morality in patients with intracerebral haemorrhage. In the prediction of mortality and short-term outcomes in patients with intracerebral haemorrhage (ICH), the ICH Score is a simple, reliable, broadly accepted grading scale. The score is a composite of admission level of consciousness (Glasgow Coma Scale score), age, and initial neuroimaging findings (hematoma volume, location, and intra ventricular haemorrhge). Objective of this study was to determine the frequency of adverse outcome (death) correctly predicted by the ICH scores in patients suffering from intracerebral haemorrhage. The ICH score was developed retrospectively and until now had not been validated for prediction of long-term functional outcome.

MATERIAL& METHOD:

This case series study was carried out at department of medicine Liaquat medical University Hospital Jamshoro and Hyderabad for a period of six months from June 16, 2012 to December 15, 2012. All the admitted patients with stroke, suspected of having ICH were considered for enrollment in the study after obtaining the informed consent and according to the predetermined inclusion and exclusion criteria. Eighty nine 89 patients were enrolled in this case series study and non-probability consecutive sampling technique was applied. Structured proforma was designed to fill the data on the basis of inclusion and exclusion criteria. Following is the inclusion criteria, Patients of stroke in adult age and confirmed cases of intra cerebral haemorrhage (Intra cerebral haemorrhage is defined as the presence of clinical focal neurological deficit>24 hours, altered sensorium, fluctuating consciousness and confirmed by CT scan findings by visualization of haemorrhage with in the cranial vault as per ICD 10, 161.x) were included in study. Patients with following criteria were excluded, Age<14 was excluded Patients of stroke other than intra cerebral haemorrhage, with meningoencephalitis and intra cranial space occupying lesion were also excluded from study after clinical and radiological evaluation. Data was analyzed on SPSS version 20. Mean and standard deviation was calculated for age, RBS, ICH score, Mean arterial pressure and systolic blood pressure. Frequencies were calculated for categorical variables like gender, GCS score category, ICH volume category, IVH, Infratentorial origin of ICH, age category and mortality. Stratification was done about age and gender. Other clinical and radiological parameters of enrolled patients in this study were also noted like Initial blood pressure, pulse pressure, mean arterial pressure and Glasgow Coma Scale (GCS). On CT scan Brain intra cerebral haemorrhage volume (ICH hematoma volume was measured on the initial head CT scan with the use of the ABC/2 method, in which A is the greatest diameter on the largest haemorrhage slice, B is the diameter perpendicular to A and C is the approximate number of axial slices with haemorrhage multiplied by the slice thickness) was recorded and presence or absence of IVH was also noted as a component of ICH score. Patients were followed up to 30 days after hospital admission. Primary outcome was taken as death within 30 days of admission.

RESULTS:

Mean age of the patients in our study was 65.14 years with the standard deviation of ±6.43 years. The minimum age was 55 years, while the maximum age was 81 years, as shown in table 1.

Table 1: Age of the patient n=89

Gender distribution shows that out of total 89 patients 56 (62.9%) were male while 33 (37.1%) were female patients as shown in figure 1.

Figure 1: Gender Distribution

Regarding age distribution 83 (93.3%) patients were <80 years of age. (Figure 2).
In this study Intracerebral haemorrhge volume was ≥30cm3 in 46(51.7%) patients as shown in figure 4 and 57(64%) patients had intra ventricular haemorrhge (IVH), while only 10 (11.2%) patients had infra tentorial haemorrhge, as shown in Figure 5 and 6.

**Figure 6: Infra tentorial haemorrhge**

In our study 32(36%) patients had ICH score ≥ 3 while 57 (64%) patients had ICH score < 3 as shown in figure 7.
Haemorrhage comprises of 10-15% of all strokes but has a variation in different parts of the world between different races but 3.0% and incidence varies according to age, sex, or intraventricular haemorrhage. Intracranial haemorrhage either cerebral haemorrhage or intracranial haemorrhage and is ischemic and hemorrhagic stroke. Hemorrhagic stroke may be blood flow to an area of the brain. Stroke is classified into deficit due to a vascular cause. Stroke results from lack of blood supply to brain tissue, which can lead to cell death. The prognosis of hemorrhagic stroke varies and studies emphasize that there is no standard or widely adequate scoring system which will help to predict prognosis of hemorrhagic stroke.

Introduction: The ICH score was developed retrospectively and improves the outcome of ICH so there should be some advances in the treatment of cerebral infarction and SAH, all infarction or subarachnoid haemorrhage [5]. Despite the ICH volume category, ICH score in case of Intracerebral hemorrhage which is defined as the presence of clinical focal neurological deficit> 24 hours, altered sensorium, fluctuating consciousness and confirmed by CT scan findings by deviation was calculated for age, RBS, ICH score, Mean blood pressure, pulse pressure, mean arterial pressure and 172.13 ±22.18 mm/Hg as shown in tables 2, 3, 4, and 5 and presence or absence of IVH was also noted as a component of ICH score. Patients were followed up to 30 days.

Gender distribution in the study of Patriota et al shows 43.9% patients were females in their study [18]. Mean RBS and systolic blood pressure in our study was found to be 145.88 ± 60.38 mg/dl and 173.8 ±22.18 mm/Hg respectively and almost Similar results were also reported 144.1 ±62.8 mg/dl and 173.8 ±35.7 mm/Hg by Patriota et al [17]. Mean age of the patients in the study of Weimar et al was 67.4 ±12 years [18]. In our study 37.1% patients were females while most of the patients were males i.e. 62.9% but 51.4% patients were females in the study of Patriota et al [17].

Gender distribution in patients with ICH score ≥3 n=32

### DISCUSSION:

Intracerebral haemorrhage (ICH) causing 10 to 15% of first-ever stroke, with 30-day mortality rate of 35 to 52% and half of the deaths reported within the first 2 days [14] [15] [16]. Mean age of the patients in our study was 65.14 ±6.43 years. Similar results were published by patriota et al in 2009, mean age in their study was 67.7 ±11.2 years [17]. Mean age of the patients in the study of Weimar et al was 67.4 ±12 years [18]. In our study 37.1% patients were females while most of the patients were males i.e. 62.9% but 51.4% patients were females in the study of Patriota et al [17].

Table 6: Age categories and mortality in patients with ICH score ≥3 n=

Regarding gender distribution mortality with ICH score ≥3, male patients were 16(80%) and 9(75%) patients were females as shown in Table 7.
CONCLUSION:

In this study frequency of adverse outcome (death) was found in 28.1% while ICH score predicted adverse outcome (death) in 36.1%. ICH score correctly predicted 77.77% adverse outcome, therefore we can conclude that the ICH score is a simple, reliable, broadly accepted grading scale. This study confirms the literature data about high mortality in ICH and reinforces the external validation of ICH Score as good prognostic tool to predict the adverse outcome in intra cerebral hemorrhagic stroke.
