Hypertension is an increasingly important medical and public health issue. In developing countries like Pakistan, India, and China, where hypertension has reached epidemic proportions affecting more than 20% of the adult population, the control rates are less than 6%. In trials comparing diuretics with other classes of antihypertensive agents, diuretics have been virtually unsurpassed in preventing the cardiovascular complications of hypertension.

Many physicians tend not to prescribe thiazide diuretics as first line antihypertensive agents recommended by most international guidelines. Low prescribing rate of thiazides has been attributed to concerns about electrolyte disturbance. Diuretics tend to be under used in management of hypertension due to concern of electrolyte imbalance. Hence, this study was conducted to determine association of hyponatremia in hypertensive patients using diuretic as an antihypertensive therapy.

This was a case control study conducted at the Aga Khan University Hospital, Karachi in adult inpatients (> 18 years) who were known hypertensive. Cases were defined as hypertensives with hyponatremia and controls were defined as hypertensives without hyponatremia. Outcome was hyponatremia. Exposed were those using diuretics. Out of 1800 hypertensive patients sampled by the ICD-9-Coding; 1191 (66%) fulfilled the inclusion criteria. Cases n (%) were 553 (46.4) and controls were 638 (53.5). Among 553 cases (%) 180 (32.5) were exposed (on diuretics) and in controls 189 (29.6) were exposed (on diuretics) p=0.15. The association of hyponatremia with diuretic use was not significant with OR=1.11 (95% CI=0.86 - 1.45, p=0.40), after adjusting for chronic kidney disease, ischemic heart disease and chronic liver disease, in the final model. Diuretics were not associated with hyponatremia in hypertensive adult patients in this study.

Hypertension is an increasingly important medical and public health issue. In developing countries like Pakistan, India, and China, where hypertension has reached epidemic proportions affecting more than 20% of the adult population, the control rates are less than 6%. In trials comparing diuretics with other classes of antihypertensive agents, diuretics have been virtually unsurpassed in preventing the cardiovascular complications of hypertension.

Many physicians tend not to prescribe thiazide diuretics as first line antihypertensive agents recommended by most international guidelines. Low prescribing rate of thiazides has been attributed to concerns about electrolyte disturbance. Diuretics tend to be under used in management of hypertension due to concern of electrolyte imbalance. Hence, this study was conducted to determine association of hyponatremia in hypertensive patients using diuretic as an antihypertensive therapy.

This was a case control study conducted at the Aga Khan University Hospital, Karachi in adult inpatients (> 18 years) who were known hypertensive. Cases were defined as hypertensives with hyponatremia and controls were defined as hypertensives without hyponatremia. Outcome was hyponatremia. Exposed were those using diuretics. Out of 1800 hypertensive patients sampled by the ICD-9-Coding; 1191 (66%) fulfilled the inclusion criteria. Cases n (%) were 553 (46.4) and controls were 638 (53.5). Among 553 cases (%) 180 (32.5) were exposed (on diuretics) and in controls 189 (29.6) were exposed (on diuretics) p=0.15. The association of hyponatremia with diuretic use was not significant with OR=1.11 (95% CI=0.86 - 1.45, p=0.40), after adjusting for chronic kidney disease, ischemic heart disease and chronic liver disease, in the final model. Diuretics were not associated with hyponatremia in hypertensive adult patients in this study.

Primary outcome variable was hyponatremia in hypertensives. Data on demographics, co-morbid conditions, type and number of antihypertensive agents and mean duration of antihypertensive therapy was recorded by trained data collectors, from the medical record of the patient. A history of physician-diagnosed diabetes, stroke, ischemic heart disease (IHD), chronic kidney disease (CKD) as documented in the medical records was noted.

Statistical Package for Social Sciences (SPSS) version 17.1 was used for the analysis. Mean and standard deviation was used for quantitative variables and
Association of hyponatremia with diuretic use in hypertensive patients

A sample of 1800 participants was drawn during the study period. Out of these, 1191 (66%) fulfilled the inclusion criteria. Cases n (%) (hypertensives with electrolyte imbalance) were 552 (46.3) and controls (hypertensives without electrolyte imbalance) were 639 (53.7). All participants were followed back in time for exposure of being on diuretics versus not on diuretics.

Mean age was 62.5 ± 12.4 years; 65.8 ± 11.1 years in cases and 59.6 ± 11.1 years in controls. Males were 540 (45.3%); 197 (35.6%) in cases and 343 (53.8%) in controls. Overall prevalence of hypertensives on exposure of being on diuretics versus not on diuretics.

Diuretics make up one of the most common causes of hyponatremia, with an estimated incidence of 11% in 1 series of 114 geriatric patients. It was found in this study that the association of hyponatremia with diuretic use in hypertensive is not significant in adults. However, there was significant hyponatremia in elderly and female patients. In the Systolic Hypertension in the Elderly Program (SHEP), which focused on older patients, hyponatremia was observed in 4.1% of patients treated with chlorothalidone versus 1.3% in the control group. In this study, this proportion of patients showed no significant association with hyponatremia.

On logistic regression analysis taking outcome hyponatremia; OR (95% CI, UCI) for association of having hyponatremia with exposure was 1.13 (0.87, 1.46, p=0.33) after adjusting for age and gender in model 1. Further adjustment for CKD, IHD and CLD is shown in model 2, 3 and 4 respectively (Table II). No significant association is shown of having hyponatremia with exposure in the final model; OR (95% CI) 1.11 (0.86 - 1.45; p=0.40).

Diuretics make up one of the most common causes of hyponatremia, with an estimated incidence of 11% in 1 series of 114 geriatric patients. It was found in this study that the association of hyponatremia with diuretic use in hypertensive is not significant in adults. stimulation of vasopressin secretion, reduced free-water clearance, and increased water intake all contribute in development of thiazide induced hyponatremia.\textsuperscript{9} Any change in these factors can hence confound the effect of thiazide induced hyponatremia. The risk of thiazide induced hyponatremia is 3-fold higher in patients older than 70 years and is higher among women, possibly because of smaller body size or lower sodium intake.\textsuperscript{10} In a study of Chinese population, in 2759 Chinese population thiazides were associated with low prevalence of hyponatremia and hence it was recommended that physicians should not deter from prescribing thiazide diuretics as first-line antihypertensive agents as recommended by most international guidelines.\textsuperscript{4}

The strength of the study is the large sample size and a case control design. It is the first to report the association of diuretics with hyponatremia in a multivariable model. However, there are several limitations in this study. Firstly, the group on thiazide diuretic is very small, hence the entire results cannot be related largely to them. Secondly, information regarding the different dosages of diuretics has not been recorded which may be a confounder. Thirdly, contribution of other agents causing hyponatremia like antidepressants causing hyponatremia has not been recorded.

It is concluded that diuretics are not associated with hyponatremia in hypertensive adult patients in this cohort of patients. However, elderly population on diuretics is more likely to have hyponatremia compared to the adult population. The use of thiazide diuretics is very low in this patient population. The authors recommend that a randomized parallel arm trial comparing thiazide diuretics with other antihypertensives be done to establish whether thiazides are associated with hyponatremia in this patient population.
